

SEED-IV Preprocessing & Feature Engineering

Rigorous Data Cleaning, Feature Extraction, & Leakage-Free Validation

SECTION 1 - Dataset Overview & Sample Balance

The SEED-IV dataset consists of preprocessed multi-channel EEG recordings collected from 15 subjects across three sessions. The dataset is used to classify four distinct emotional categories: neutral, sad, fear, and happy. We verify the window-level and subject-level sample balance configurations. Subject contributions are perfectly balanced, with exactly 2,505 windows extracted per subject. The class distributions are reasonably balanced with modest variations (Neutral: 10,170, Sad: 10,245, Fear: 9,225, Happy: 7,935), with Happy samples being somewhat underrepresented due to stimulation duration constraints.

Figure 1: SEED-IV sample distribution configurations across classes, subjects, and sessions.

SECTION 2 - Feature Value Distribution & Standardization

The raw Differential Entropy (DE) feature values exhibit substantial scale and distribution differences across the five frequency bands (Delta, Theta, Alpha, Beta, Gamma) when averaged across the 62 channels. Higher bands show higher power ranges and wider variances. This requires standardizing features to a mean of 0 and standard deviation of 1. To prevent data leakage, scaling parameters are fit strictly on training trials, then transformed on validation/testing data, keeping test characteristics unseen during training.

Figure 2: Distribution of raw DE values across the 5 spectral bands.

Figure 3: DE feature distribution before (Raw) and after (Standardized) scaling.

SECTION 3 - Feature Extraction Pipeline & Selection

The feature extraction pipeline transforms raw EEG signals into spatial-spectral features. Filtered bands are partitioned into 4-second windows. Differential Entropy is computed for a Gaussian distribution as: $DE = 0.5 * \log(2 * \pi * e * \sigma^2)$. A Linear Dynamical System (LDS) is then applied to smooth the DE values across time. We select the DE + LDS variant over PSD and moving average alternatives, as DE provides logarithmic normalization matching human sensory characteristics, while LDS models temporal dynamics without lag.

SEED-IV Data Preprocessing and Feature Extraction Pipeline

Figure 4: SEED-IV data preprocessing and feature extraction pipeline flowchart.

Feature Extraction Variant Selection Matrix

DE + LDS (SELECTED FEATURE) Differential Entropy (DE) models the logarithmic energy characteristics of EEG matching human perception. Linear Dynamical System (LDS) effectively filters noise while preserving long-term temporal dynamics in brain states.	PSD + LDS Power Spectral Density (PSD) measures linear power scales. Combined with LDS smoothing, it lacks logarithmic normalization, making it sensitive to amplitude spikes and outliers.
DE + Moving Average Differential Entropy smoothed using a simple moving average. and is sensitive to transient artifacts.	PSD + Moving Average Power Spectral Density smoothed with moving average. Weakest combination: highly sensitive to high-amplitude noise, lacking temporal state-space modeling.

SECTION 5 - Trial-Level Splitting & Durations

Preventing data leakage is essential for obtaining reproducible model evaluations. In sliding-window EEG protocols, adjacent windows share up to 90% overlapping samples. If splitting is performed at the individual window level, near-duplicate samples from the same trial leak across the train and test splits, causing artificially inflated accuracies. To ensure a leakage-free protocol, we enforce trial-level splitting: every window from a given trial is assigned entirely to either the train or test set. This trial duration variance justifies window-level modeling and sliding window sequences over padding or truncating whole trials, which would introduce excessive zero-padding.

Trial-Level Stratified Cross-Validation Splitting Protocol vs. Window Leakage

One Subject's 24 Trials (SEED-IV Session Protocol)

T1 (Train)	T2 (Train)	T3 (Train)	T4 (Train)	T5 (Train)	T6 (Train)	T7 (Train)	T8 (Train)
T9 (Train)	T10 (Train)	T11 (Train)	T12 (Train)	T13 (Train)	T14 (Train)	T15 (Train)	T16 (Train)
T17 (Train)	T18 (Train)	T19 (Train)	T20 (Test)	T21 (Test)	T22 (Test)	T23 (Test)	T24 (Test)

DATA LEAKAGE WARNING

Window-Level Splitting (AVOIDED):

- Adjacent windows share overlapping samples due to sliding.
- Splitting adjacent windows between Train and Test leaks temporal information, inflating evaluation accuracy artificially.

Trial-Level Splitting (IMPLEMENTED):

- Entire trials are separated. No window overlaps across Train and Test, guaranteeing genuine zero-leakage evaluation.
